## ABSTRACT

The most popular method for transporting fluids and gases is through pipelines nowadays. Regular inspection is necessary for the pipelines to work correctly. Humans must not enter potentially dangerous environments to inspect these pipelines. As a result of this, pipeline robots came into existence. These pipe inspection robots help in pipeline inspection, protecting numerous people from harm since human beings cannot enter the pipes and inspect them in case there is any such or kind of damage that requires repair. Despite numerous improvements, pipeline robots still have several limitations. The introduction of this in pipe inspection robots helps to solve many problems, such as leakage of the gas or fluid pipelines, rustiness, and also if the pipe is broken from any part.

Key words: Broken, Inspection robot, Leakage, Pipeline

### **INTRODUCTION**

### **Robotic IPIR**

Pipelines are now the most widely used method of transport for gases and liquids (63-65). Therefore, ongoing pipeline monitoring is necessary to assure its safety and health.<sup>[1]</sup> The most widely non-destructive testing utilized inspection techniques are optical testing, radiographic testing, ultrasonic testing, and hydrostatic testing, among others.<sup>[2]</sup> However, because of recent advancements in robotic technology,<sup>[66,67]</sup> they are now the preferable choice. Robots are a superior choice because it is challenging for people to access a small pipeline.<sup>[3]</sup> In-Pipe Inspection Robots (IPIR) have undergone a great deal of improvement recently, and these advancements are categorized according to their various locomotion patterns. Figure 1 shows examples of the pipeline inspection gauge (PIG),<sup>[9,10]</sup> screw,<sup>[16,17]</sup> inchworm,<sup>[18-24]</sup> wall press,<sup>[25-29]</sup> walking,<sup>[30-34]</sup> caterpillar,<sup>[35-39]</sup> and wheel type.<sup>[40-52]</sup> These popular forms of movement have drawbacks in addition to their benefits.<sup>[53]</sup>

Address for correspondence: Muhammad Ahmad Baballe E-mail: mbaballe@kanopoly.edu.ng The PIG type can be utilized for large distances<sup>[4,8]</sup> and moves inside pipelines using water pressure. The inside surface of the pipelines are not harmed by the screw-helical type's motion when it moves.<sup>[11-15]</sup> The inchworm may pass through pipelines because of its strong grasp despite its poor traction.<sup>[18-22]</sup> The wall press type steadily passes through the pipelines using contact force.<sup>[25-29]</sup> The walking kind employs legs to move and has a complex mechanism, which causes reduced surface wear and slippage.<sup>[30,34]</sup> Caterpillars move inside pipelines using tracked wheels, and its system enables them to adjust to the circumstances there.<sup>[35-39]</sup> The wheel type is more mobile than the other varieties and can travel inside pipelines by simply rotating its wheels.<sup>[40-44]</sup> Due to the pipeline's curved and branching pipes, these robots must overcome numerous obstacles. It encounters motion singularity and erratic motion while doing this.<sup>[5-7]</sup>

## **Motion singularity**

The "Motion Singularity" is the loss of contact between a robot and pipeline intersections such

Figure 1: Different types of in-pipe inspection robots

curved pipes, L-branch pipes, and T-branch pipes.<sup>[54,55]</sup> Due to its powerful traction force and substantial contact area, the caterpillar robot offers more stability and is the most widely used IPIR. The pipeline is kept in contact with the inner surface no matter how the pipeline is turning using tracked wheels.<sup>[35,39,54,55]</sup> If one of the wheels loses contact with the inner surface of the pipe, it is unable to pass through it, leading to motion singularity.<sup>[54]</sup> In Figure 2, a caterpillar robot that is travelling through T-branch pipes uses two modules in place of one to prevent motion singularity. Three caterpillar wheels are mounted on the first module at a 120° angle to one another, and the second module is infix at a  $60^{\circ}$  angle to the front module.<sup>[54]</sup> A pipeline exploration robot named "FAMPER" loses contact with the inner surface of the pipeline while turning at Y and T-branch pipes, which results in motion singularity. The caterpillar wheels were positioned at a  $5^{\circ}$  inclination with regard to the robot body rather than set straight to compensate for the loss of contact. "Motion singularity" is thereby avoided.<sup>[55]</sup> A two-wheel chain robot that avoids the motion singularity is shown in.[56]

#### **Irregular motion**

According to published research, many conventional wheeled robots use wheels that are symmetrically positioned at a 120° angle to ensure even loading and improved stability while moving through pipelines. The wall press characteristic is how the wheeled robots acquire this stability.<sup>[35,54,57,59]</sup> According to,<sup>[41,42]</sup>

Figure 2: Two-module collaborative indoor pipeline inspection robot

the inclusion of six wheels corrects the uneven motion that occurs along the circumferential axis of the pipeline in forward motion caused by the three-wheel arrangement in wheeled IPIR. The wheeled robot has a three-wheel layout and moves inside the pipelines using two different types of wheels.<sup>[24,58,63-65]</sup> One has single wheels, whereas the other has double wheels, as seen in Figure 3. When moving forward, the robot's single threewheel design tries to rotate in the pipeline's circumferential direction.<sup>[60]</sup> Only straight pipelines have been the subject of investigations about their motion. The orientation of the robot at the completing end is different from the starting end in circumstances<sup>[61]</sup> where it tries to roll over to maneuver through the curved pipeline. In addition, steering inside branching pipes is challenging due to how the wheels are positioned. To avoid motion singularity and irregular motion while retaining the same orientation before and

Figure 3: Three-wheel configuration robot

after entering the curved pipeline, this research focuses on constructing a wheeled IPIR with a single three-wheel arrangement.<sup>[62]</sup>

# Contribution

To address the issue of irregular motion and motion singularity occurring in pipelines, a wheeled type IPIR is proposed and developed in this research. The wheels on this robot are different from those on conventional robots in that they are not fixed at a 120° angle from one another. The location of the wheels guarantees that the robot's wheels are always in contact with the pipe surface and prevents the robot from rolling over when moving along a curved pipeline. It also aids the robot's navigation through branched pipes.<sup>[62]</sup>

# **RESOURCES AND TECHNIQUES**

Initially, we used the Solidworks program to design the robot. To ADAMS, the created model is exported. Using the limitations listed in the flowchart, motion analysis is performed for the robot. The findings are then discussed. Links, wheels, clamps, a central shaft, legs, a spring, a fixed joint, and a prismatic joint are all features of the proposed robot. Inside pipelines, the legs provide improved stability. The legs are supported by the small linkages. All of the parts are kept where they belong thanks to the clamps. The wheels are designed to increase mobility within pipelines. All of the modular parts are linked to the central shaft, which serves as the primary body. The prismatic joint, which is the moveable joint and the one that generates the force required for the wheels to make contact with the inner surface of the pipeline, moves while the fixed joint remains stationary. Spring-based devices that compress and expand in accordance with the inner circumference of the pipeline supply the necessary force for the prismatic junction. The internal pipeline diameter of the robot can range from 250 mm to 350 mm. It has three revolute joints and one prismatic joint. By compressing and stretching the legs, these joints provide the robot extra stability as it travels through the pipelines. It helps the robot deal with various pipeline scenarios, such curved or T-branch pipes. The actuator scale is ascertained using static analysis.

# **DISCUSSION/ANALYSIS**

The ADAMS software does the motion analysis. The robot design is imported from Solidworks and the boundary conditions for the simulation are provided by the ADAMS software. Body-to-body contact, motor rpm, and spring stiffness are taken into account. Simulations are done for the proposed robot as well as the conditions when the wheels are offset by 120°. In the scenario, the robot first travels inside a 350 mm-diameter pipeline. After traveling 600 mm, the pipeline's inner diameter changes; it decreases by 10 mm, or 340 mm overall. The robot's capacity to adjust to pipelines of various diameters is tested by this shift in diameter. The robot then passes through a straight pipe once more before coming to a 90° curved elbow. It enters the straight pipe once more after leaving the curved pipe to exit the pipeline. This simulation scenario tests the robot's ability to move through pipes that are straight, curved, and of different diameters. The only difference between the simulations' parameters is the angle at which the wheels are mounted. Gravity, motor speed, solid body contact, and spring stiffness are the criteria the robot must meet in order to travel through the pipelines. The third wheel serves as a support wheel, making the three wheels at the bottom of the robot's front side functional. The robot has three inactive wheels at the back. The motor spins at 100 rpm, and the spring stiffness is 2.826 N/mm.

## Robot with wheels for pipe inspection

Traditional wheeled IPIRs have wheels that are 120° apart from one another. The angle is calculated

between the centers of each wheel and the central axis of the robot body. The homogeneous wheel mounting angle results in the motion singularity. The prismatic junction between the three legs allows them to compress uniformly as they pass through the pipeline. Motion singularity consequently develops inside curved pipelines. Wheel 1 rotates with a greater angular velocity than wheels 2 and 3, which remain stationary. The three wheels' angular velocity is constant as the inner diameter of the pipe shrinks. The robot then attempts to enter the curved pipeline, but wheel 3 loses contact, preventing the robot from doing so. It demonstrates that wheel 3's angular velocity, which should have been high when it traversed the concave region of the pipe, has remained constant in magnitude. The fact that it lost contact with the pipe wall is thus demonstrated. A maximum force of approximately 11.25 N is applied to wheels 1, 2, and 3 as the robot goes through a 350 mm pipeline. Wheels 1 and 2 encounter the most force when the pipeline diameter is increased to 340 mm, whilst wheel 3 experiences a decrease in forces. The forces pulling on the wheels then cease to exist. Wheel 3 experiences an increase in force when the robot enters the curved pipeline because the wheel loses touch with the concave portion of the inner pipeline surface. When the robot tries to travel through a curved pipe, it loses contact with one of the wheels and is unable to do so; however, the two wheels that are still in contact exert a force on the spring, which is why wheel 3 has a high spike after losing contact. The spring force causes the wheels to push the robot backward, which causes wheel 3 to hit the inside of the pipe and generate a huge force spike. Here, springs 1 and 2 refer to the springs in the front and back of the robot, respectively. When the robot passes through a pipeline with a 350 mm inner diameter, the force supplied by springs 1 and 2 ranges from 1.25 to 12.5 N. When the inner pipeline diameter reaches 340 mm, the force generated by springs 1 and 2 approaches 17.5 N. The robot cannot move through the curved pipeline because of motion singularity, which causes the force in spring 1 to decrease. Motion singularity causes the back half to exert a slight push at that precise moment because of the inertia of motion. As a result, the legs on the robot's back compress, producing a strong force of roughly 25 N at first before progressively reducing. It moves at an average

AJCSE/Jan-Mar-2022/Vol 7/Issue 1

linear velocity of 0.35 m/s while inside the 350 mm straight pipeline. The linear speed of the robot varies between 0.30 and 0.35 m/s when the inner diameter of the pipeline drops to 340 mm. The robot then tries to enter the curved pipeline but is unable to do so due to motion singularity, causing a sharp fall in linear velocity.

## Wheeled IPIR design modification

The suggested wheeled design Inspection of the Pipe, the wheels are asymmetrically and at various angles mounted by the robot. The arrangement of the wheels results in angles that are 120°, 104.88°, and 135.12° apart from one another. Calculations are made to determine the angle between the central axes of each wheel and the body of the robot.

In the curved pipeline, a robot With the exception of the wheel mounting angle, it uses the same mechanism as a conventional robot with wheels. The motion singularity in the curved pipeline is therefore avoided by the suggested design. The angular velocity of all three wheels remains constant as the robot moves through a straight pipeline with an inner diameter of 350 mm. When the inner pipeline diameter was reduced to 340 mm, small spikes in angular velocity were observed. After then, it moves via a straight pipeline with a constant angular velocity for the three wheels. The angular velocity of wheel 3 increases while that of wheels 1 and 2 decreases as the robot moves along the curved pipeline. Wheel 3 has a higher magnitude than the other two wheels because it travels through the concave portion, which causes its angular velocity to increase. This demonstrates that the robot's wheels are in contact with the ground as it travels through the bent conduit. After leaving the curved pipe, it enters a straight pipeline where the three wheels' angular velocities are held constant. As they go along the curved pipeline, there are increased forces on all three wheels. The forces ranging from 2.5 to 10 N are equally distributed among the three wheels. The springs utilized in the front and back of the robot are numbered 1 and 2, respectively. When going through a straight pipe with an inner diameter of 350 mm, spring 1 exerts a force of 11 N. When the inner diameter of the pipe is reduced to 340 mm, spring 1's force increases to 17.25 N. The robot travels through the

curved pipe with a force of 15.65 N being applied by spring number one. It enters the straight pipe after leaving the curved one, providing the same spring 1 force of 17.25 N. Spring 2 follows the same pattern as it moves through the pipeline. The robot moves at a linear speed of 0.39 meters per second inside a straight pipeline with an inner diameter of 350 millimeters. It then has a linear velocity of 0.36 m/sec when the inner diameter is changed to 340 mm. The speed of the object falls off as it approaches the convex portion of the curved pipeline wheels 1 and 2. As the wheel moves through the concave portion of the curve pipe, its speed increases. It recovers to 0.36 m/s in speed as it re-enters the straight pipeline. Until it exits the pipeline, it keeps moving at this constant speed. The robot moves at an average speed of 0.33 m/s across both straight and curved pipes because its velocity cannot be determined directly because the three wheels have various magnitudes there. All three wheels are moving inside a straight pipeline with an inner diameter of 350 mm, and the angular velocity is constant for all three. Even after reducing the inner diameter to 340 mm, this remained the same. It departs from the straight pipeline and then merges with the curved pipeline. Wheels 1 and 2 are moving at an angle as they pass through the concave portion of the pipeline. Wheel 3 also experiences a decrease in angular velocity when it passes through the concave portion of the pipeline. Wheel 2's greater angular velocity suggests that it was in contact with the pipeline's inner surface and so prevented motion singularity. After leaving the curved tunnel, it proceeds into a straight pipeline, where all three wheels' angular velocities stay constant. The forces pulling on all three wheels of the robot rise as it travels through the curved pipeline. With forces ranging from 2.5 N to 12 N, the forces applied on all three wheels are roughly similar. While entering a 350 mm inner diameter pipeline, spring 1's 11 N force remains constant. As the pipeline's inner diameter decreases to 340 mm, the spring's first force rises to 17.25 N. The spring force then decreases to 15.5 N while passing through the curved pipeline, and when it re-enters the straight pipeline, it rises to 17.25 N. Spring 2 follows this same force trend as it travels through the pipeline. Robot travels at a speed of 0.39 meters per second as it passes a straight pipeline with an inner diameter of 350 millimeters. The robot moves at a speed of 0.36 meters per second when its inner diameter is reduced to 340 mm. Wheels 1 and 2 move more quickly through the bent pipeline as wheel 3 moves less quickly. Wheel 2 travels through the pipeline's concave portion, while Wheel 3 travels through the pipeline's convex portion, causing the increase and decrease. When the robot enters the straight pipeline, its speed drops to 0.36 meters per second. The robot moved at an average speed of 0.33 m/sec both inside the straight and curved pipelines.

## **ROBOTS FOR INSPECTING PIPELINES**

- 1. Extreme security: Use the pipeline robot to enter the pipeline to efficiently discover the interior conditions of the pipeline or remove any concealed dangers. Because of the high labor intensity and greater safety risks associated with manual labor, these jobs are not good for employees' health. The Easy Sight pipeline robot's intelligent operation may significantly enhance the operation's performance in terms of safety
- 2. Labor-saving: Small and lightweight, the pipe inspection robot can be controlled by one person. The controller can be put on the vehicle, which will save time and room
- 3. Increased effectiveness and caliber: The smart pipeline robot from Easy Sight can display real-time data such date and time, crawler inclination (pipeline slope), air pressure, crawling distance (meters of line), laser measurement results, and azimuth in addition to accurate positioning (optional). The function keys allow you to control the clock display of the lens angle of view as well as the display status of this information (positioning of pipeline defects)
- 4. Great level of protection: There is no need to be concerned about the pipe camera's quality because it has a high level of protection, airtight protection, and the material is waterproof, anti-rust, and corrosion resistant
- 5. Receiving and releasing cables will not interfere with one another with a high-precision cable reel, and the length is configurable. The pipe inspection robot can inspect pipelines with diameters ranging from 100 mm to 2000 mm. It can raise productivity and save labor in addition to enhancing task precision.

In addition, it can maintain the pipeline in some locations where manual labor is not appropriate and quickly identify the internal sources of pipeline degradation.<sup>[68]</sup>

### CONCLUSION

In this work, we contrast the suggested wheeled type IPIR with the wheeled type IPIR that is currently in use. The three wheels are mounted on the current design at a 120° angle from one another. Both the suggested and conventional wheeled forms of IPIR are simulated. The ideal angles are 104.88°, 135.12°, and 120°. Results of velocity and force analyses for each wheel demonstrate how this design brings the wheels into contact with the pipelines. The created robot did not experience the unequal force experienced by the robot with a wheel mounting angle of 120° when traversing the curved pipeline. Also discussed are the effects of the in-pipe wheel robots.
